- ## Self Introduction

"Hello, my name is **Sathish P**, and I am based in **Bangalore**.

I hold a Bachelor's degree in Commerce (**B.Com**) from **SRN Adarsh College**. Early in my career, I worked as an **Operations Executive at Vindhya E-Infomedia**, where managing daily processes sparked my deep interest in working with data to find patterns and drive efficiency.

To transition into this field, I first completed the **Google Data Analyst** and **Google Data Analyst with Python** certifications, learning tools like Google BigQuery, Advanced Excel, Tableau, R, and Python. Seeking a stronger, hands-on foundation, I then completed a comprehensive **Data Analyst course at Besent Technologies**, mastering **MySQL Workbench, Advanced Excel, Power BI, Tableau, Python, Statistics, and Machine Learning**.

As part of my training, I successfully built and deployed **8 real-time, end-to-end data analyst projects** which are fully documented in my portfolio. I am now eager to bring my analytical skills, technical toolkit, and operational background to an entry-level **Data Analyst** role where I can add value from day one."

- ## Year Gap

"After graduating in 2022, I started my career as an Operations Executive at Vindhya E-Infomedia. Working closely with operations made me realize how crucial data-driven decision-making is for businesses. To pivot into this field purposefully, I decided to build a rock-solid technical foundation. I first earned my Google Data Analyst certifications and then pursued an intensive, hands-on Data Analyst program at Besent Technologies through October 2026, mastering tools like SQL, Python, Power BI, and Machine Learning while building 8 real-time projects. This period wasn't just a gap—it was a focused transition to build deep technical expertise so I could enter the analytics industry job-ready."

- **Projects Explained:**

1. End-To-End Churn Analytics & Customer Intelligence

1. **The Problem**: The company wanted to understand why customers were canceling their plans, which users were most likely to leave, and how much monthly revenue was being lost.

2. **Data & Cleaning (Python & SQL)**: I worked with three separate tables—customer details, subscription logs, and support complaints. Using Python and SQLite, I combined these tables, cleaned up formatting issues (like standardizing gender fields and handling missing country values), and created a new column called a churn_flag to easily track who canceled and who stayed.

3. **Analysis & Key Insights:**I calculated that the overall Churn Rate was around 28.57%, meaning the company was losing a noticeable chunk of its user base.When breaking it down by plan type, I found that the Basic plan had the highest churn rate (60%) compared to Premium plans.I also found a strong 0.77 correlation between customer support escalations and churn—meaning customers who raised angry complaints were heavily prone to canceling their subscriptions.

4. **Visualizations & Business Recommendation**: I built visual charts using Matplotlib and Seaborn (such as correlation heatmaps and trend lines) to showcase these findings. Based on this, I recommended that the business introduce special retention offers specifically for Basic plan users and prioritize quick resolution for escalated support complaints to prevent customers from leaving."*

2. General Store Transaction Database & Audit

Business Goal: To analyze retail transaction data, evaluate regional performance, identify high-profit segments, and manage store operational health using advanced SQL queries.

1. The Problem: The management team wanted deep insights into store performance—specifically looking at which sub-categories and regions generated high sales versus hidden losses, and tracking the performance of regional managers.

2. Data Filtering & Conditional Logic (WHERE & Filtering): I wrote queries to filter high-value corporate orders (e.g., checking sales over $500 and profits) and used logical operators (AND, OR, IN, BETWEEN) to narrow down specific states like California and New York. I also checked data cleanliness by verifying missing postal codes using IS NULL.

3. Advanced SQL (Joins & Subqueries):

- I used **GROUP BY and HAVING** clauses to filter sub-categories generating over $50,000 in sales.
- I utilized **INNER JOIN and LEFT JOIN** to connect sales tables with a regional managers table to find out which managers (like Roxanne Jones or Fred Thompson) were responsible for specific sales.
- I wrote **subqueries** (nested queries) to pull transactions performing higher than regional averages or to isolate cities running at a net loss.

4. Business Insight & Recommendation: My analysis revealed that certain high-volume sub-categories like Bookcases and Tables had massive sales volumes but negative net profits due to heavy discounting. I recommended restructuring discounts on low-margin furniture items to protect overall company profitability."*

3. Global Airbnb Performance & Market Analytics

Project Title: Global Airbnb Performance Analysis Dashboard

Business Goal: To analyze global listing trends, regional market shares, host trust profiles, and customer seasonality across 10 major cities to understand platform growth and guest behavior.

1. The Problem: The goal was to track how Airbnb grew over the years, which cities held the largest market share, what factors drove customer satisfaction ratings, and how seasonal travel patterns fluctuated.

2. Key Insights & Dashboard Features:

- **Growth & Lifecycle:** Using a historical trend chart, I mapped Airbnb's lifecycle phases from its takeoff point to its peak in new listings around 2015, followed by regulatory impacts and the COVID-19 pandemic drop.

- **Market Share:** Through a Pareto analysis chart, I found that **Paris, New York, and Sydney** account for nearly half of all listings and 59% of total reviews, with Paris leading largely because traditional hotel rooms there are twice as expensive as Airbnb.

- **Ratings & Trust:** I integrated a rating breakdown matrix showing that Mexico City and Rio de Janeiro had the best overall guest ratings, while cleanliness and value for money often scored the lowest. I also analyzed host verification metrics, showing that over two-thirds of hosts are fully verified.

- **Seasonality:** Using a seasonal chart, I highlighted that European cities like Paris and Rome peak during summer (April to August), whereas New York spikes during the winter holiday season (November–December).

3. Business Recommendation: Based on these insights, I recommended that marketing campaigns target seasonal shifts proactively and that customer success teams focus on improving property cleanliness standards in lower-rated regions to protect host revenue."*

- **How would you investigate a sudden drop in sales/revenue for a company?**

Step 1: Validate the Data First (Data Integrity Check)

- Before panicking about business performance, I would check if it's a technical or data pipeline error. Did the tracking pixel break? Did the database fail to refresh? Did automated ETL scripts fail yesterday?

Step 2: Isolate the Drop (The 'Where' and 'Who')

- Using SQL or a dashboard tool, I would break down the revenue trend by dimensions like Region, Product Category, Customer Segment, and Device Type.
- I'd want to know: Is this drop happening everywhere, or is it isolated to one specific city (e.g., a logistics failure in the South region) or one specific product line (e.g., a drop in Furniture sales)?

Step 3: Check Internal Business Factors

- I would look at operational and marketing metrics. Did website traffic drop? Did conversion rates fall? Were there pricing changes, stock-outs of popular items, or an increase in customer support complaints/escalations that caused shoppers to abandon carts?

Step 4: Check External Macro Factors

- Finally, I would look at external variables—such as seasonality, new competitor activity entering the market, or macro-economic shifts.

Conclusion / Action: Once I pinpoint the root cause—for example, discovering that mobile app conversion dropped due to a checkout bug—I would present those findings to the product and management teams so they could fix it immediately."*

- **"When presenting technical insights to a non-technical manager,"**

1. Use the 'Bottom-Line Up Front' (BLUF) Method:
I start with the main conclusion right away. Instead of saying "My Random Forest model achieved 88% accuracy," I say, "We are at risk of losing ₹74K in monthly revenue due to customer churn, and I found the main reason why."

2. Avoid Technical Jargon:
I leave out terms like p-values, inner joins, or hyperparameter tuning. Instead, I use plain business language like trends, customer segments, loss drivers, and efficiency.

3. Tell a Visual Story:
I use clear visualizations—like clean bar charts or trend lines built in Power BI or Tableau—to guide them through the data naturally. For example, showing a simple bar chart that proves Basic-plan users have a 60% cancellation rate makes the problem self-explanatory.

4. Provide Actionable Recommendations:
Managers don't just want to know what happened; they want to know what to do next. I always end by offering clear, data-driven options—such as recommending that we target retention offers specifically toward high-risk basic subscribers."*
